

Overview: To enable the web application to parse the social media public reviews into the application database global schema, an interpretation of the representation of the public review data is required. There are two examples shown to demonstrate how to map the json responses to the attributes in the database.

Example 1: In this example of http request response from Google place API search (<https://developers.google.com/places/documentation/details#PlaceDetailsResponses>). From this Google place search example, Table-1 (Database – Public posting data relationship) shows how the data element equivalent in the database.

“Place Details responses are returned in the format indicated by the `output` flag within the request's URL path.”[1]

Diagram illustrating the structure of a Google Places API result, showing the mapping of JSON fields to a hierarchical tree structure.

To integrate to the application database attributes, each relevant attribute element is mapped from the hierarchy of the nodes from the graph. To denote the hierarchy of the relationship, parent node precedes the child node. Each parent-child pair is separated by a dot("."). See example 1 (Table 1) and example 2 (Table 2) below.
